ABSTRACTS

This study was conducted to survey the status of birds in islands off the west coast of Seogwipo City – Beomseom, Hyeongjeseom, Marado, and Gapado islands – in May and September 2013, as a part of the joint research of the Korean Biodiversity Consortium. As a result, 56 species were observed in those four islands: 167 individuals of 15 species on Beomseom, 79 individuals of 13 species on Hyeongjeseom, 193 individuals of 21 species on Gapado, and 354 individuals of 42 species on Marado; where seven threatened birds were confirmed to inhabit there. *Apus pacificus* is dominant on Beomseom, Hyeongjeseom, and Marado while *Passer montanus* is dominant on Gapado. Species diversity was highest on Marado (2.54) which was followed by Gapado and Beomseom (1.99) and Hyeongjeseom (1.82). These findings will be used as valuable data to protect the biota of the islands off Seogwipo including Beomseom that was a state-designated natural reserve.

Introduction

Jeju Special Self-governing Province was designated as one of the world biosphere reserves, the world natural heritage sites, and the global geoparks by United Nations Educational, Scientific and Cultural Organization is a region with superior biodiversity and landscape resources. Jejudo Island has its own unique living creatures adapted to its unique environment as a volcanic island. The island is distributed of any and all plants zones ranging from warm-temperate forests to sub-alpine plants and maintains the ecological environment from seashore intertidal zones through parasitic cones (*oreum* in Jeju language), *gotjawal* (the world's one and only unique forests or volcanic topology on Jejudo Island with tropical northern and southern limit plants co-existing), and valley forests to the forests zones in Hallasan Mountain (Kim et al., 2012). Particularly, since the island is located in the southernmost part of the Korean peninsula and used as a wintering, breeding, and middle

stopover for migratory birds, the survey findings in Jeju are given significant attention. Recently, biodiversity has sharply decreased due to climate change, reckless catching and collection, introduction of exotic species, destruction of habitats, and increase in pollution sources; among these factors, particularly; climate change is expected to have significant influence on the change in biota in a certain region. In this regard, Jejudo Island would be an optimal place to monitor the movement of habitats of those birds that are assumed attributable to climate change and destruction of habitats.

This study was conducted as a part of the joint academic survey of the National Biodiversity Institutions Association in order to understand the status of birds that appear on and around the islands off the west coast of Seogwipo City – Beomseom Island, Hyeongjeseom Island, Marado Island, and Gapado Island – and to prepare the primary data to establish the protective measures to conserve biodiversity in case of the future climate change and so on. So far, the previous studies on the birds in the west coast areas of Seogwipo City were conducted, for example, by: Park (1990), Park and Oh (1991), Oh et al. (1994, 2002), Oh (2014), Park and Kim (1996), Kim (2001, 2008), Kim and Lee (2002), and Kim et al. (2010c).

Materials and methods

Research sites

Research sites are the islands of Seogwipo City including Beomseom Island, Hyeongjeseom Island, Gapado Island, and Marado Island, all off the west coast of Seogwipo City (Figure 1).

Beomseom Island belongs to Beophwan-dong, Seogwipo, an uninhabited island 1.3 kilometers away from Beophwanpogu Port, which is long circle shape in a north-south direction with 440 m long between its east and west and 520 m long between its south and north on the area of 0.84 km². The vegetation in the island includes: *Misanthus sinensis*, *Machilus thunbergii*, *Castanopsis cuspidata* var. *sieboldii* and *Pinus thunbergii*. Hyeongjeseom Island belongs to Andeok-myeon, Seogwipo City, an uninhabited island 5.5 kilometers away from Sagyerihang Port, which consists of two islands in a north-south direction and the north one of which has the area of 48,061 m² and the south one of which is 4,945 m². Its vegetation is rather sparse and its seashore consists of weathered shell and gravels. Gapado Island belongs to Daejeong-eup, Seogwipo, an inhabited island 2.2 kilometers away from Moseulpohang Port, which is 1.4 km long in a north-south direction and 1.5 km in an east-west direction on the area of 0.84 km². In the middle of the island grow barleys while a coast road was paved along the seashore. Marado Island belongs to Daejeong-eup, Seogwipo, which is an inhabited island 7.8 kilometers south away from Moseulpohang Port in the southwest of Jejudo Island as well as situated in the southernmost location of the Korean territory. The island forms longer in a north-south direction having east high west low topology. Marado Island is 500 m long in an east-west direction but 1,300 m long in a north-south direction on the area of 0.3 km². Its coastline consists of sea cliff and a total of 24 sea caves have developed along its coastline (Kang, 2004). Most of the land is the plains consisting of grass while in the center of the island develop the colonies of *Pinus thunbergii* and *Misanthus sinensis*.

Method

The on-site and literature surveys were conducted in parallel: the on-site survey was conducted in a way to survey the species and

their number of individuals appearing on each island and surrounding waters before coming on shore and then to survey those while walking around each island or walking through narrow trails after coming on shore. The surveyors used the observation tools such as telescope (40×) and binoculars (10×) to grasp each species and the number of individuals in a way of naked eye examination, twittering, nasute, excrement and trace of nests, and check of bodies and so on. The survey period was from 27 May through 31 May, 2013 during spring and from 2 September through 6 September, 2014 during autumn.

When analyzing the community of individual populations, dominance value (Simpson, 1949) and species diversity (Shannon and Weaver, 1949) were analyzed on the entire appearing species; while the number of individuals by season was recorded of the largest number observed in the survey once regardless of the frequency of monthly surveys, in the following way.

1) Dominance (Dom.)

$\text{Dom.} = (\text{ni}/\text{N}) \times 100\% / (\text{ni}: \text{Number of observed individuals of the } \text{i}^{\text{th}} \text{ species; N: Total number of individuals})$

2) Species Diversity (H')

$H' = -\sum(\text{ni}/\text{N}) \times \ln(\text{ni}/\text{N}) / (\text{ni}: \text{Number of observed individuals of the } \text{i}^{\text{th}} \text{ species, N: Total number of individuals})$

Results and discussion

As a result, the species observed on four islands were a total of 56 species: 16 species and 167 individuals on Beomseom Island, 13 species and 79 individuals on Hyeongjeseom Island, 21 species and 193 individuals on Gapado Island, and 42 species and 354 individuals on Marado Island (Table 1). The species commonly observed on those four islands include 3 species such as: *Egretta sacra*, *Falco peregrinus*, *Apus pacificus*, *Hirundo rustica*, *Locustella pleskei*, and *Monticola solitarius* while the species observed only on one island include 35 species such as *Anas poecilorhyncha*, *Gavia stellata*, *Butorides striata*, *Bubulcus ibis*, *Egretta garzetta*, *Pernis ptitorhynchus*, *Accipiter soloensis*, *Butastur indicus*, *Himantopus himantopus*, *Actitis hypoleucus*, *Heteroscelus brevipes*, *Calidris subminuta*, *Calidris alpina*, *Synthliboramphus wumizusume*, *Columba janthina*, *Cuculus micropterus*, *Halcyon pileata*, *Alcedo atthis*, *Upupa epops*, *Oriolus chinensis*, *Dicrurus macrocercus*, *Terpsiphone atrocaudata*, *Cisticola juncidis*, *Urosphena*

Species diversity (H')		1.99	1.82	1.99	2.54	2.65	

squamiceps, *Acrocephalus orientalis*, *Phylloscopus inornatus*, *Phylloscopus borealis xanthodryas*, *Phylloscopus tenellipes*, *Muscicapa griseisticta*, *Muscicapa sibirica*, *Muscicapa dauurica*, *Cyanoptila cyanomelana*, *Motacilla flava*, *Coccothraustes coccothraustes*, and *Emberiza cioides*. The dominant species observed were: 68 individuals of *Apus pacificus* on Beomseom Island (40.72%) followed by 22 individuals of *Zosterops japonica* (13.17%) and 17 individuals of *Locustella pleskei* (10.18%); 35 individuals of *Apus pacificus* (44.30%) on Hyeongjeseom Island followed by 16 individuals of *Hirundo rustica* (20.25%) and 7 individuals of *Anas poecilorhyncha* (8.86%); 83 individuals of *Passer*

montanus (43.01%) on Gapado Island followed by 30 individuals of *Hirundo rustica* (15.54%) and 27 individuals of *Apus pacificus* (13.99%); and 122 individuals of *Apus pacificus* (34.46%) on Marado Island followed by 58 individuals of *Passer montanus* (16.38%) and 22 individuals of *Bubulcus ibis* (6.21%). Species diversity was indicated the highest on Marado Island (2.54) followed by Gapado and Beomseom Islands (1.99) and Hyeongjeseom Island (1.82).

Compared to the previous studies (Park, 1990, Park and Kim, 1996, Kim and Lee, 2002, Oh, 2006, Oh et al., 2010, Oh, 2014) on Beomseom Island, one species of *Alcedo atthis* was added;

compared to [Kim and Lee \(2002\)](#) on Hyeongjeseom Island, 7 species were added including *Gavia stellata*, *Ixobrychus sinensis*, *Falco peregrinus*, *Synthliboramphus wumizusume*, *Halcyon pileata*, *Hirundo rustica*, and *Locustella pleskei*. 3 species found on Beomseom Island – *Ixobrychus sinensis*, *Synthliboramphus wumizusume*, and *Halcyon pileata* – were the remains of feather, assumed to be attacked by falcons. Compared to the survey by [Kim \(2001\)](#) on Gapado Island, 3 species were added including *Falco peregrinus*, *Cuculus canorus*, and *Pica pica* while compared to [Kim \(2008\)](#) and [Kim et al. \(2010c\)](#) on Marado Island, 4 species were added including *Himantopus himantopus*, *Butastur indicus*, *Chlidris subminuta*, and *Coccothraustes coccothraustes*, respectively. In the meantime, comprehending the previous literature surveys and this survey confirmed a total of 171 species observed on those 4 islands off coast of Seogwipo ([Appendix 1](#)).

This survey confirmed 7 species of threatened birds such as *Falco peregrinus*, *Pernis ptitorhynchus*, *Accipiter soloensis*, *Columba janthina*, *Terpsiphone atrocaudata*, *Synthliboramphus wumizusume* and *Locustella pleskei* ([Table 2](#)). *Falco peregrinus* was observed on the islands of Hyeongjeseom, Gapado, and Marado, respectively; particularly found 3 young birds on Hyeongjeseom Island. *Falco peregrinus* is a resident bird breeding steep cliffs of oreum or sea cliffs on Jeju Island ([Kim et al., 2010a, Kim, 2013](#)). This species indicates the narrow scope of feeding activities within 300 m during breeding period ([Ikeda et al., 1990](#)) but tends to expand the scope of activities up to oreums located in the middle mountain areas or the subalpine zone of Hallasan Mountain after such breeding period. Rapacious birds prefer to sea cliffs, some of mountain rocks, and forests as their breeding site while some of rapacious birds consider distance to water resources, species of trees for nesting, height and breast height of those species of trees for nesting, degree of the developments of surrounding vegetation, and lower layer structure when selecting a breeding site ([Titus and Mosher, 1981](#)). Thus, it is suggested that the natural breeding sites on seashore of (un)inhabited islands off coast Jeju Island – an optimal breeding place for *Falco peregrinus* – be managed for conservation.

In addition, 3 species with higher mobility were observed on Marado Island including *Pernis ptitorhynchus*, *Accipiter soloensis*, and *Butastur indicus*, these rapacious birds of which are migratory birds passing through Jejudo Island mostly in spring and autumn. Since Jejudo Island holds the habitat environment ranging from coast intertidal zones, farmlands, oreum, and subalpine zones – where those rapacious birds can secure their views – as well as is being situated in a geopolitical location, it is being used as a middle stopover or wintering place for rapacious birds with higher mobility. As revealed in the previous studies reporting that the western and southern islands area including Jejudo Island in Korea

are used as a major immigration route for rapacious birds ([Kwon et al., 2006, Kim, 2009, Choi et al., 2009](#)), [Kim et al., 2010b, 2011a](#)), considering Jejudo Island to be an important location as their breeding place or middle stopover, any artificial threatening factors against them should be minimized.

Columba janthina is a species distributing on and around uninhabited islands in the East Asia including Korea and Japan, mostly breeding in subtropical and warm temperate evergreen forests ([Baptista et al., 1994](#)). According to the survey conducted by [Oh et al \(1994\)](#), *Columba janthina* lays eggs from early March through middle of May and incubates egg for 18 days and broods over egg for about 30 days. This species lays only one egg and broods over the egg mostly in the species of tree such as *Sambucus sieboldiana*, *Litsea japonica*, *Elaeagnus macrophylla*, *Machilus thunbergii*, and *Pinus thunbergii*; and feeds fruits and leaves of trees showing a variety of selective feeds depending on fruiting season of fruits of trees. The species distributes on Jeju Island particularly on its islands such as Beomseom, Seopseom, Munseom, Jigwido, Marado, Chujado, and Sasudo ([Park and Kim, 1996, Kim, 2006, Oh et al., 2010, Kim and Oh, 2009, Kim et al., 2010c](#)) while being observed on Beomseom Island in this survey.

Locustella pleskei is a summer bird breeding on the surrounding islands of Jeju Island, found on 4 areas including the islands of Beomseom, Hyeongjeseom, and Marado during this survey. *Terpsiphone atrocaudata* is also a summer bird breeding mostly in the valleys of Hallasan Mountain or gotjawal forests on Jejudo Island ([Kim et al., 2011b](#)), found one individual on Marado Island. *Synthliboramphus wumizusume* tends to form a group with a few individuals in the waters around Marado Island ([Kim, 2008](#)) and seems to be sometimes attacked by falcons, which was confirmed on Hyeongjeseom Island with the trace of bodies predated by falcons during this survey.

Recently, as the number of tourists visiting Jejudo Island becomes increasingly greater, the types of tourism such as tracking of *olle* esplanades, cruise ship tourism, and fishing leisure activities seem to increase more and more. Since the bird fauna of the region isolated as an island indicates the trend of change in biological species depending on the changes in ecological environment of the island or climate change, it is of ecological importance. In particular, the region of islands is smaller – accounting for only 3% – compared to the area of land on earth; however, to such an extent as to about 15% of all known birds or plants until now existing on islands, it is of higher biological value ([Whittaker, 1998](#)). Furthermore, the success rate of breeding and the habitat preference may be negatively affected by the entrance of people in case of the birds breeding on islands. The (un)inhabited islands off west coast Seogwipo City – the survey sites during this survey – are being used as a breeding site of certain birds including *Falco peregrinus*, *Columba janthina*, *Egretta sacra*, *Monticola solitaires*, and *Locustella pleskei*. The four survey islands were all selected as a breeding site for *Egretta sacra* and *Monticola solitaires*, among which *Egretta sacra* is a white heron preferring to sea cliffs with shelves much more developed ([Kim et al., 2005](#)). Therefore, protecting the wild birds inhabiting on Jejudo Island including (un)inhabited islands off coast Seogwipo City requires continuing the elimination of any intervening factor by humans, the ban on damaging to the original habitats, and the monitoring of rare birds and so on. In addition, the areas in and around Seogwipo City in the southernmost location in Korea are the optimal place to detect the appearance of subtropical birds that tend to go northwards due to climate change. Since there are some evidences that subtropical birds come to Jeju Island in such consecutive cases as the first success of breeding by *Ardea cinerea* in Jungmun-dong, Seogwipo City in April 2013 and the exhaustion of *Sula leucogaster* in the waters of Seogwipo City in June 2013

including the appearance of *Dicrurus macrocercus* on Marado Island during this survey, it is required to conduct more specific monitoring on the frequency of appearance of subtropical birds and the status of breeding, and the future possibility for the breeding of the species that has yet to breed on Jeju Island.
